Overview of The Subject Area

Problem Statement: Using machine learning, how might we predict areas at risk for deforestation such that we can protect and sustain the health of our planet?

Granularity: Year over year change as CO2 levels as carbon cycle much better tracked this way as well as numerical canopy density data.

- Also focuses on spatial granularity like regions such as country.

Model Output: Ideal output of a model is to predict potential areas at risk for deforestation based on carbon emission and tree coverage.
(potential to include climate data)

Vision for Tackling the Problem using Data Science

Next Point Forecast ML model would help predict carbon emissions and or tree cover density changes for high risk areas

- Main reach for this kind of model is for environmental companies or government agencies to help with sustainability goals or controlled logging
- The metric to add value or success is the models ability and accuracy to predict CO2 and canopy density such that a reduction in annual deforestation occurs
- Model quality can be measure through scikit-learn's train_test_split

**Next Point
Forecast**

An Estimate of the potential impact of such a solution

Big Picture: While we aim to improve the health and sustainability of our planet through forest conservation efforts, these models can also help companies decide appropriate logging areas that have less of an impact on the ecosystem relative to other areas

Other Benefits:

- Early startup companies can benefit for agriculture or infrastructure growth such that they take a green approach or adhere to environmental regulations
- Detection of illegal logging for quicker responses from authorities

An introduction to the Dataset

Dataset:

- Global Forest Watch uses dashboards and interactive maps that take on real-time data on (CO2, canopy density, etc)
- Smaller environmental datasets due to its geographical nature

Quality Concerns:

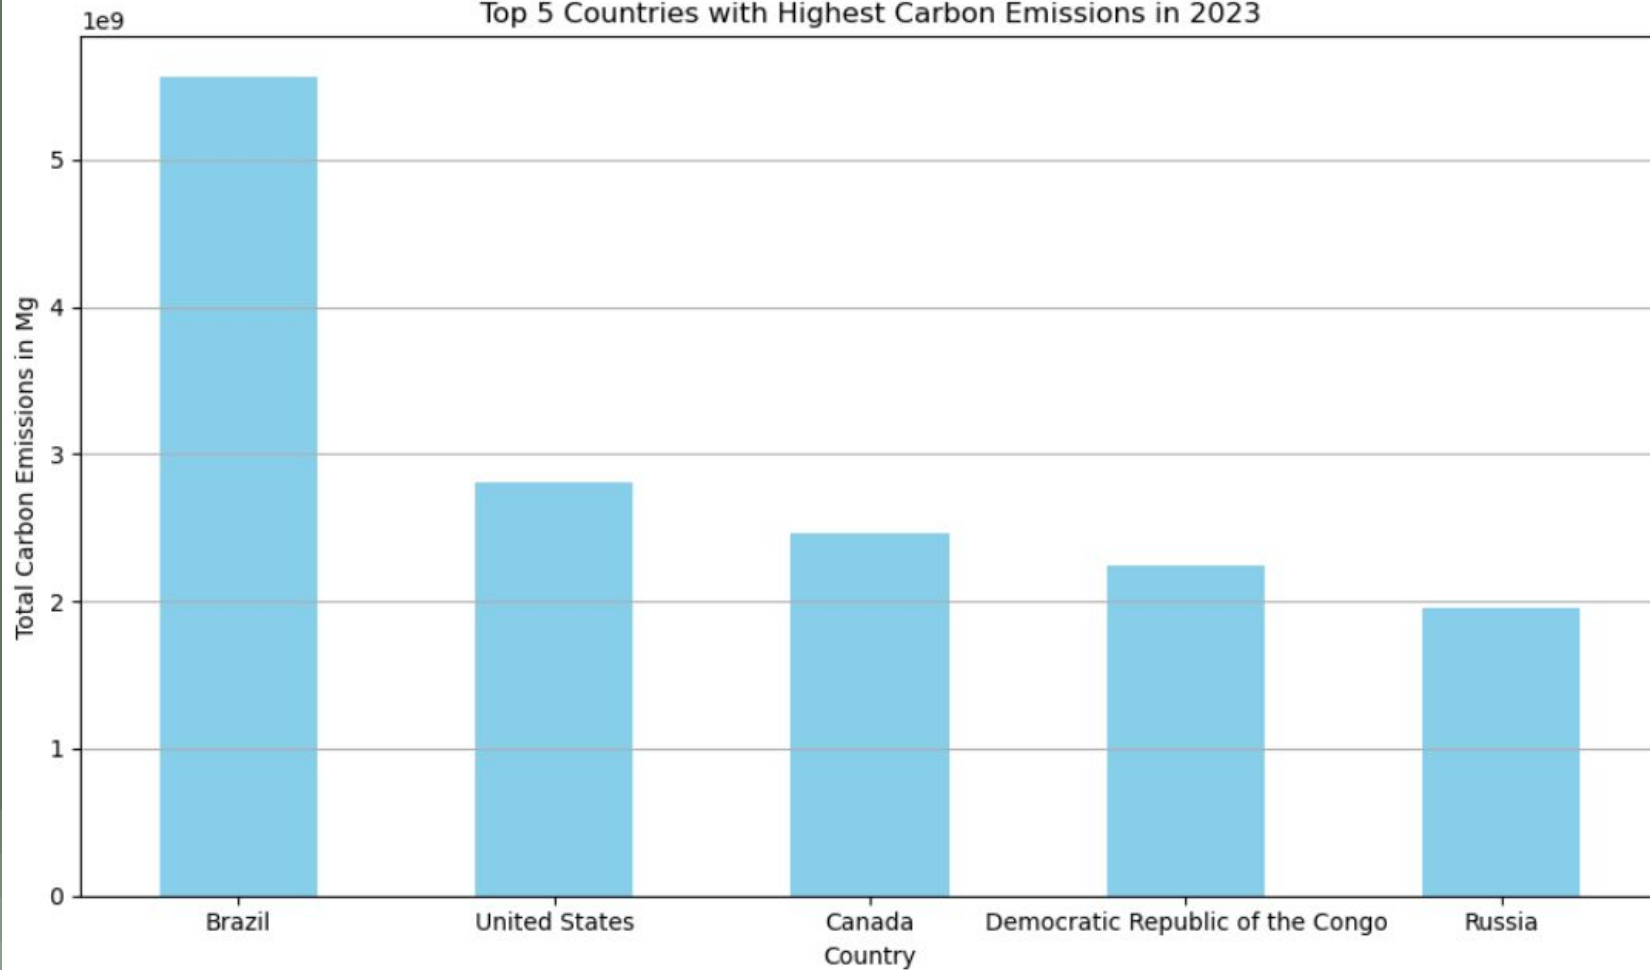

- Had a lot of nulls because it excluded 30 threshold and less
- More robust model might require additional datasets like climate (temperature)

Preliminary EDA Findings:

- Gradual canopy density loss over the years (spike in 2015-2016)
- Brazil followed by Canada are huge carbon emitters

Top 5 Countries with Highest Carbon Emissions in 2023

Top 5 Countries with Highest Carbon Emissions in 2022

Total Tree Canopy Loss between 2001-2023

Next steps in Feature Engineering & Modeling

Evaluation criteria: is to ensure high-level documentation and reproducibility including comprehensive assumption and context of the analysis

Feature Engineering:

- Year-over-year change
- Rolling averages,
- Additional datasets (climate/temperature)

Baseline modeling:

- Time series Analysis
 - Target variables: net carbon emissions/canopy density
 - Output: Regions in risk of deforestation
-
